

## ABSTRACT

A composite reverse osmosis membrane is described, which includes a polyamide skin layer on a porous support, with a contact angle between the 5 polyamide skin layer surface and water of 45 ° or less. The composite reverse osmosis membrane has a high salt rejection and also a high water permeability. This composite reverse osmosis membrane is produced by forming a polyamide skin layer on a porous support having the steps of: forming a layer on the porous support by coating a solution A including one or 10 more compounds having at least two reactive amino groups; contacting the layer with a solution B comprising one or more polyfunctional acid halide compounds; and subsequently, contacting the layer with a solution C comprising the polyfunctional acid halide compound of a higher concentration than the solution C. The concentration of the polyfunctional acid halide 15 compound in the solution C is preferably at least 1.2 times of the solution B.
